Chapter 43

The Immune System

PowerPoint® Lecture Presentations for

Biology

Eighth Edition
Neil Campbell and Jane Reece

Lectures by Chris Romero, updated by Erin Barley with contributions from Joan Sharp

Overview: Reconnaissance, Recognition, and Response

- Barriers help an animal to defend itself from the many dangerous pathogens it may encounter
- The immune system recognizes foreign bodies and responds with the production of immune cells and proteins
- <u>Two</u> major kinds of <u>defense</u> have evolved: innate immunity and acquired (adaptive) immunity

- Innate immunity is present before any exposure to pathogens and is effective from the time of birth
- It involves <u>nonspecific</u> responses to pathogens
- Acquired immunity, or <u>adaptive immunity</u>, develops <u>after exposure to agents</u> such as microbes, toxins, or other foreign substances
- It involves a <u>very specific response</u> to pathogens

Innate Immunity of Vertebrates

- The immune system of mammals is the best understood of the vertebrates
- Innate defenses include <u>barrier defenses</u>, <u>phagocytosis</u>, <u>antimicrobial peptides</u>
- Additional defenses are unique to vertebrates: the inflammatory response and natural killer cells

Pathogens (microorganisms and viruses)

INNATE IMMUNITY

- Recognition of traits shared by broad ranges of pathogens, using a small set of receptors
- Rapid response

Barrier defenses: Skin Mucous membranes Secretions

Internal defenses:
Phagocytic cells
Antimicrobial proteins
Inflammatory response
Natural killer cells

ACQUIRED IMMUNITY

- Recognition of traits specific to particular pathogens, using a vast array of receptors
- Slower response

Humoral response: Antibodies defend against infection in body fluids.

Cell-mediated response: Cytotoxic lymphocytes defend against infection in body cells.

Barrier Defenses

- Barrier defenses include the <u>skin</u> and <u>mucous membranes</u> of the respiratory, urinary, and reproductive tracts
- Mucus traps and allows for the removal of microbes
- Many body fluids including <u>saliva</u>, <u>mucus</u>, and <u>tears</u> are hostile to microbes
- The low pH of skin and the digestive system prevents growth of microbes

Antimicrobial Peptides and Proteins

- Peptides and proteins function in innate defense by attacking microbes directly or impeding their reproduction
- Interferon proteins provide innate defense against viruses and help activate macrophages

Inflammatory Responses

- Following an injury, mast cells release histamine, which promotes changes in blood vessels; this is part of the inflammatory response
- These changes <u>increase local blood supply</u> and <u>allow more phagocytes and</u> <u>antimicrobial proteins to enter tissues</u>
- Pus, a fluid rich in white blood cells, dead microbes, and cell debris, accumulates at the site of inflammation

- Inflammation can be either local or systemic (throughout the body)
- Fever is a <u>systemic inflammatory response</u> triggered by <u>pyrogens</u> released by <u>macrophages</u>, and <u>toxins from pathogens</u>
- Septic shock is a life-threatening condition caused by an overwhelming inflammatory response

Natural Killer Cells

- All cells in the body (except red blood cells)
 have a class 1 MHC (Major
 histocompatibility complex) protein on their
 surface
- Cancerous or infected cells no longer express this protein; natural killer (NK) cells attack these damaged cells

Concept 43.2: In acquired immunity, lymphocyte receptors provide pathogen-specific recognition

- White blood cells called lymphocytes recognize and respond to antigens, <u>foreign</u> <u>molecules</u>
- Lymphocytes that mature in the thymus above the heart are called T cells, and those that mature in bone marrow are called B cells
- Lymphocytes contribute to immunological memory, an enhanced response to a foreign molecule encountered previously

11

- B cells and T cells have <u>receptor proteins</u> that can bind to foreign molecules
- Each individual lymphocyte is specialized to recognize a specific type of molecule
- An antigen is any foreign molecule to which a lymphocyte responds
- A single B cell or T cell has about 100,000 identical antigen receptors

 Lymphocytes bind to specific antigens in blood, lymph nodes, spleen, tonsils, mucosa

B cells:

- Provide humoral immunity
- Plasma cells secrete antibodies

- Functions of antibodies
- Antibodies activate complements groups of plasma proteins
- Antibodies <u>block sites on viruses and bacterial</u> <u>exotoxins</u>
- Antibodies cause agglutination (clumping of cells) and precipitation (soluble molecules come out of solution)

T-cells

- T-cells provide cell-mediated immunity
- Activated by antigen-presenting cells (APCs)
- APCs phagocytize antigens, thus presenting antigen to T-cells to activate them

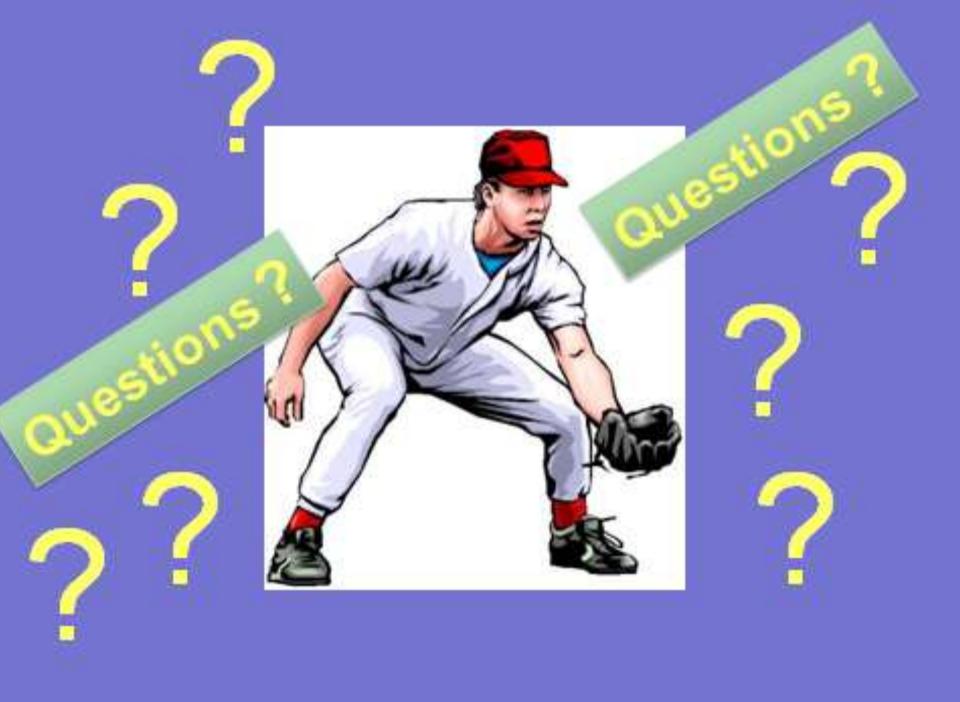

Antigen presentation by an Top view: binding surface MHC molecule exposed to antigen receptors **Antigen Class I MHC Antigen** molecule **Plasma**

- Helper T cells: stimulate proliferation of other T cells and B cells, signaling antibody production to begin
- Cytotoxic T cells: attack and kill foreign cells
- The first exposure to a specific antigen represents the primary immune response
- Next exposures to the same antigen are cold secondary immune response
- Memory T cells: in the secondary immune response, memory cells <u>facilitate a faster, more</u> <u>efficient response</u>

Thank you for your attention and participation!

You should now be able to:

- Distinguish between innate and acquired (adapted) immunity
- 2. Describe the inflammation response
- Distinguish between the following pairs of terms: antigens and antibodies; B lymphocytes and T lymphocytes; primary and secondary immune responses; humoral and cell-mediated response;
- Describe the cellular basis for immunological memory

ZU
